1.Student Result System

Problem Statement

Check whether a student **passed or failed** based on marks.

Real-time Example

Used in college result portals and systems used by companies like TCS for training assessments.

Code:

```
marks = int(input("Enter marks: "))
if marks >= 35:
    print("Pass")
else:
    print("Fail")
```

2. **Login Authentication System**

Problem Statement

Check whether **username and password are correct**.

Real-time Example

Every website uses login verification.

Python Code

```
username = "admin"
password = "1234"
u = input("Enter username: ")
p = input("Enter password: ")
if u == username and p == password:
    print("Login Successful")
else:
    print("Invalid Credentials")
```

3. **Find Common Students in Two Courses**

Problem Statement

Two courses have student lists. Find students **enrolled in both courses**.

Real-Time Example

University portals track course registrations.

Code

```
course1 = ["Rahul","Anil","Priya","Kiran"]
course2 = ["Priya","Kiran","Sita","Ravi"]
common_students = list(set(course1) & set(course2))
print("Students in both courses:", common_students)
```
